

tmux on Ctrl-Space

~/config/tmux/tmux.conf · tmux 3.7b · every binding below is live on this machine

PREFIX

ctrl

+

space

- C-b is unbound

panes run fish, not the login zsh

windows & panes count from 1, and renumber when one closes

mouse on - click to focus, drag a border to resize, wheel to scroll

no colours of its own - the terminal's theme comes through untouched

50 000 lines of scrollbar per pane, status bar on top

j set by your config

o stock tmux, still bound

ctrl held with the key, no prefix

Tap the prefix, let go, then press the key. Rows that need no prefix say so.

[sessions]

a session survives the terminal closing

_ from the shell

tmux start an unnamed session

tmux new -s work start one called "work"

tmux a attach to the most recent

tmux a -t work attach to a named one

tmux ls list what is running

tmux kill-session -t work end one

Continuum restores your last layout automatically when the server starts, so you rarely start from nothing.

_ key bindings

f project picker - fuzzy-find any git repo under ~/personal or ~/projects, newest commit first, and jump to a session rooted there (opens in a popup)

s tree of every session and window, with a live preview bounce to the last session (stock tmux puts this on L, which you reassigned to resizing)

shift + tab next session

) previous session

(rename this session

\$ detach - leaves everything running

d pick which client to detach

D

[windows]

tabs inside a session

_ key bindings

c new window, opened in the current pane's directory

tab bounce to the last window

n next window

p previous window

1 - 9 jump to a window by number

w choose a window from a tree

, rename this window

. renumber it

' jump by index, typed at a prompt

& kill this window (asks first)

The current window is shown bold in the status bar rather than tinted - the config sets no colour, so your terminal theme decides.

[panes]

splits - the active one has a blue border

_ split & move

| split to the right, same directory

- split below, same directory

h j k l move left / down / up / right - hold the prefix once and keep tapping

← ↓ ↑ → the same, on arrow keys

o cycle to the next pane

; bounce to the last pane

q show pane numbers, type one to jump

_ size & rearrange

H J K L resize by 5 cells, also repeatable

z zoom this pane full-screen, again to undo

space cycle through the stock layouts

{ } swap this pane with the one before / after

! pop this pane out into its own window

x kill this pane (asks first)

% and " still split too, but the new pane opens wherever you launched tmux from, not where you are standing. That is the whole reason | and - exist.

[copy mode]

vi keys - no prefix once you are inside

_ getting in and out

[enter copy mode

wheel scrolling up enters it for you (no prefix) - unless the program in the pane wants the scroll itself

q leave copy mode

l paste the tmux buffer back

_ selecting

v start a selection

V select whole lines

ctrl + v switch to a rectangular block

y copy to the macOS clipboard and exit

enter copy to the tmux buffer only - not the system clipboard

esc drop the selection, stay in copy mode

_ moving & searching

h j k l move the cursor

w b forward / back a word

H L top / bottom of the visible screen

g top of the scrollbar

G back to the bottom

/ search downward

? search upward

n N next / previous match

With the mouse: drag to select and it lands on the clipboard when you let go - no keys involved.

[config & plugins]

tpm · resurrect · continuum

_ reload & inspect

r reload the config, with a confirmation message

? list every binding that is live

:

_ saved layouts

ctrl + s save every session, window and pane - including what is on screen

ctrl + r restore the last save by hand

Continuum saves on a timer and restores on server start, so the manual keys are a safety net rather than a routine.

_ plugins

I install anything newly added to the config

U update installed plugins

alt + u remove plugins no longer in the config

Four stock bindings were reassigned and given new homes: l and L moved to tab and shift+tab, f became the project picker, r became reload.
